

LECTURE 3: BASIC NETWORK PROPERTIES AND WEB GRAPH

CSWP4641: Social Information Network Analysis and Engineering
Wednesday February 11th 2015

Structure of Networks?

Network is a collection of objects where some pairs of objects are connected by links

What is the structure of the network?

Components of a Network

- **Objects:** nodes, vertices
- **Interactions:** links, edges
- **System:** network, graph

N
 E
 $G(N, E)$

Networks or Graphs?

- **Network** often refers to real systems
 - Web, Social network, Metabolic network
 - Language:** Network, node, link
- **Graph:** mathematical representation of a network
 - Web graph, Social graph (a Facebook term)
 - Language:** Graph, vertex, edge

We will try to make this distinction whenever it is appropriate, but in most cases we will use the two terms interchangeably

Networks: Common Language

Choosing Proper Representation

- **Choice of the proper network representation determines our ability to use networks successfully:**
 - In some cases there is a unique, unambiguous representation
 - In other cases, the representation is by no means unique
 - The way you assign links will determine the nature of the question you can study

Choosing Proper Representation

- If you connect individuals that work with each other, you will explore a **professional network**
- If you connect those that have a sexual relationship, you will be exploring **sexual networks**
- If you connect scientific papers that cite each other, you will be studying the **citation network**
- If you connect all papers with the same word in the title, you will be exploring what? It is a network, nevertheless

NETWORK PROPERTIES: HOW TO CHARACTERIZE A NETWORK?

Undirected vs. Directed Networks

Undirected

- Links: undirected (symmetrical)

- Examples:
 - Collaborations
 - Friendship on Facebook

Directed

- Links: directed (arcs)

- Examples:
 - Phone calls
 - Following on Twitter

Connectivity of Graphs

Connected (undirected) graph:

- Any two vertices can be joined by a path.
- A disconnected graph is made up by two or more connected components

Bridge edge: If we erase it, the graph becomes disconnected.

Articulation point: If we erase it, the graph becomes disconnected.

Connectivity of Directed Graphs

Strongly connected directed graph

- has a path from each node to every other node and vice versa (e.g., A-B path and B-A path)

Weakly connected directed graph

- is connected if we disregard the edge directions

Graph on the left is connected but not strongly connected (e.g., there is no way to get from F to G by following the edge directions).

Directed Graphs

Two types of directed graphs:

Strongly connected:

- Any node can reach any node via a directed path

DAG – Directed Acyclic Graph:

- Has no cycles: if u can reach v , then v can not reach u

- Any directed graph can be expressed in terms of these two types!

Strongly Connected Component

Strongly connected component (SCC)

is a set of nodes S so that:

- Every pair of nodes in S can reach each other
- There is no larger set containing S with this property

Strongly connected components of the graph: $\{A, B, C, G\}$, $\{D\}$, $\{E\}$, $\{F\}$

Adjacency Matrix

$A_{ij} = 1$ if there is a link from node i to node j
 $A_{ij} = 0$ otherwise

$$A = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix} \quad A = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \end{pmatrix}$$

Note that for a directed graph (right) the matrix is not symmetric.

Node Degrees

15

Directed

Source: node with $k^{\text{in}} = 0$
 Sink: node with $k^{\text{out}} = 0$

Node degree, k_i : the number of edges adjacent to node i
 $k_A = 4$

Avg. degree: $\bar{k} = \langle k \rangle = \frac{1}{N} \sum_{i=1}^N k_i = \frac{2E}{N}$

In directed networks we define an **in-degree** and **out-degree**.

The (total) degree of a node is the sum of in- and out-degrees.

$$k_C^{\text{in}} = 2 \quad k_C^{\text{out}} = 1 \quad k_C = 3$$

$$\bar{k} = \frac{E}{N} \quad \bar{k}^{\text{in}} = \bar{k}^{\text{out}}$$

Complete Graph

The **maximum number of edges** in an undirected graph on N nodes is

$$E_{\text{max}} = \binom{N}{2} = \frac{N(N-1)}{2}$$

A graph with the number of edges $E = E_{\text{max}}$ is a **complete graph**, and its average degree is $N-1$

Networks are Sparse Graphs

Most real-world networks are sparse

$$E \ll E_{\text{max}} \quad (\text{or } \bar{k} \ll N-1)$$

WWW (Stanford-Berkeley):	$N=319,717$	$\langle k \rangle=9.65$
Social networks (LinkedIn):	$N=6,946,668$	$\langle k \rangle=8.87$
Communication (MSN IM):	$N=242,720,596$	$\langle k \rangle=11.1$
Coauthorships (DBLP):	$N=317,080$	$\langle k \rangle=6.62$
Internet (AS-Skitter):	$N=1,719,037$	$\langle k \rangle=14.91$
Roads (California):	$N=1,957,027$	$\langle k \rangle=2.82$
Protein (S. Cerevisiae):	$N=1,870$	$\langle k \rangle=2.39$

(Source: Leskovec et al., Internet Mathematics, 2009)

Consequence: Adjacency matrix is filled with zeros!

(Density (E/N^2) : WWW= 1.51×10^{-5} , MSN IM = 2.27×10^{-8})

More Types of Graphs:

Unweighted
(undirected)

$$A_{ij} = \begin{pmatrix} 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

$$A_{ij} = 0 \quad A_{ij} = A_{ji}$$

$$E = \frac{1}{2} \sum_{i,j=1}^N A_{ij} \quad \bar{k} = \frac{2E}{N}$$

Examples: Friendship, Sex

Weighted
(undirected)

$$A_{ij} = \begin{pmatrix} 0 & 2 & 0.5 & 0 \\ 2 & 0 & 1 & 4 \\ 0.5 & 1 & 0 & 0 \\ 0 & 4 & 0 & 0 \end{pmatrix}$$

$$A_{ij} = 0 \quad A_{ij} = A_{ji}$$

$$E = \frac{1}{2} \sum_{i,j=1}^N \text{nonzero}(A_{ij}) \quad \bar{k} = \frac{2E}{N}$$

Examples: Collaboration, Internet, Roads

More Types of Graphs:

Self-edges (self-loops)

$$E = \frac{1}{2} \sum_{i,j=1}^N A_{ij} + \sum_{i=1}^N A_{ii}$$

Examples: Proteins, Hyperlinks

Multigraph

$$E = \frac{1}{2} \sum_{i,j=1}^N \text{nonzero}(A_{ij})$$

Examples: Communication, Collaboration

Network Representations

WWW >> directed multigraph with self-interactions

Facebook friendships >> undirected, unweighted

Citation networks >> unweighted, directed, acyclic

Collaboration networks >> undirected multigraph or weighted graph

Mobile phone calls >> directed, (weighted?) multigraph

Protein Interactions >> undirected, unweighted with self-interactions

Bipartite Graph

Bipartite graph is a graph whose nodes can be divided into two disjoint sets U and V such that every link connects a node in U to one in V ; that is, U and V are independent sets.

Examples:

- Authors-to-papers (they authored)
- Actors-to-Movies (they appeared in)
- Users-to-Movies (they rated)

"Folded" networks:

- Author collaboration networks
- Movie co-rating networks

Degree Distribution

Degree distribution $P(k)$: Probability that a randomly chosen node has degree k

$$N_k = \# \text{ nodes with degree } k$$

Normalized histogram:

$$P(k) = N_k / N \rightarrow \text{plot}$$

Distance in a Graph

Distance (shortest path, geodesic)

between a pair of nodes is defined as the number of edges along the shortest path connecting the nodes

■ If the two nodes are disconnected, the distance is usually defined as infinite

In **directed graphs** paths need to follow the direction of the arrows

■ Consequence: Distance is not symmetric:

$$h_{A,C} \neq h_{C,A}$$

Network Diameter

Diameter: the maximum (shortest path) distance between any pair of nodes in a graph

Average path length for a connected graph (component) or a strongly connected (component of a) directed graph

$$\bar{h} = \frac{1}{2E} \sum_{i,j=1}^N h_{ij} \quad \text{where } h_{ij} \text{ is the distance from node } i \text{ to node } j$$

■ Many times we compute the average only over the connected pairs of nodes (we ignore "infinite" length paths)

Finding Shortest Paths

Breadth-First Search:

- Start with node u , mark it to be at distance $h_u(u)=0$, add u to the queue
- While the queue not empty:
 - Take node v off the queue, put its unmarked neighbors w into the queue and mark $h_u(w)=h_u(v)+1$

Clustering Coefficient

Clustering coefficient:

- What portion of i 's neighbors are connected?
- Node i with degree k_i
- $C_i \in [0,1]$

$$C_i = \frac{2e_i}{k_i(k_i - 1)}$$

where e_i is the number of edges between the neighbors of node i

□ **Average Clustering Coefficient:** $C = \frac{1}{N} \sum_i C_i$

Key Network Properties

Degree distribution: $P(k)$

Path length: h

Clustering coefficient: C

STRUCTURE OF THE WEB
GRAPH

Web as a Graph

Q: What does the Web "look like"?

Here is what we will do next:

- We will take a real system (i.e., the Web)
- We will collect lots of Web data
- We will represent the Web as a graph
- We will use language of graph theory to reason about the structure of the graph
- Do a computational experiment on the Web graph
- **Learn something about the structure of the Web!**

Web as a Graph

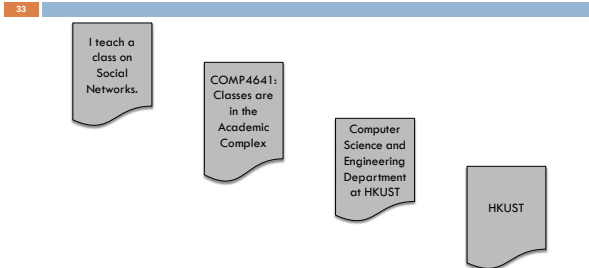

Q: What does the Web "look like" at a global level?

Web as a graph:

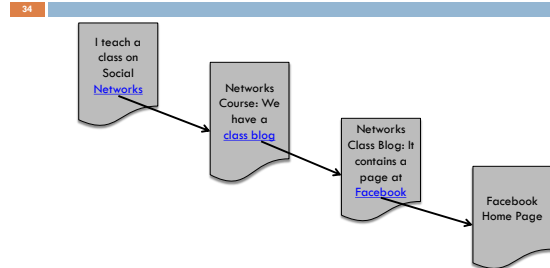

- Nodes = web pages
- Edges = hyperlinks
- Side issue: What is a node?
 - Dynamic pages created on the fly
 - "dark matter" – inaccessible database generated pages

The Web as a Graph

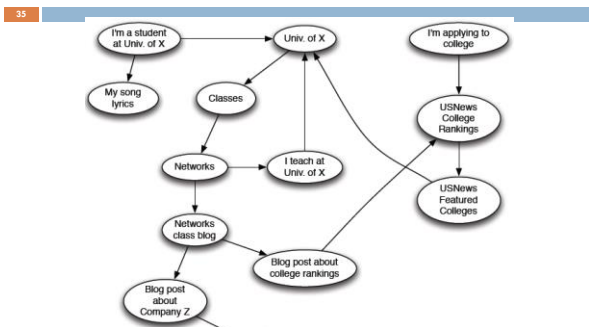

The Web as a Graph

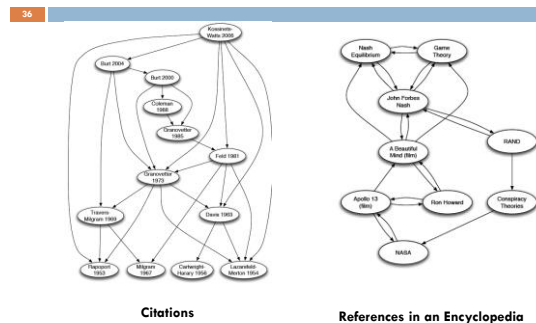

- In early days of the Web links were **navigational**
- Today many links are **transactional**

The Web as a Directed Graph

Other Information Networks

What Does the Web Look Like?

- 37
- How is the Web linked?
 - What is the "map" of the Web?
- Web as a directed graph** [Broder et al. 2000]:
- Given node v , what can v reach?
 - What other nodes can reach v ?

For example:
 $In(A) = \{A, B, C, E, G\}$
 $Out(A) = \{A, B, C, D, F\}$

Graph Structure of the Web

- 38
- There is a giant SCC
 - There won't be 2 giant SCCs
 - Heuristic argument:
 - It just takes 1 page from one SCC to link to the other SCC
 - If the 2 SCCs have millions of pages the likelihood of this not happening is very very small

Structure of the Web

39

Broder et al., 2000:

- Altavista crawl from October 1999
 - 203 million URLs
 - 1.5 billion links
- Computer: Server with 12GB of memory
- **Undirected version of the Web graph:**
 - 91% nodes in the largest weakly conn. component
 - Are hubs making the web graph connected?
 - Even if they deleted links to pages with in-degree >10 WCC was still ≈50% of the graph

Question about the bias coming from the BFS nature of crawling the graph.

Structure of the Web

40

Directed version of the Web graph:

- **Largest SCC:** 28% of the nodes (56 million)
- Taking a random node v
 - $\text{Out}(v) \approx 50\%$ (100 million)
 - $\text{In}(v) \approx 50\%$ (100 million)
- What does this tell us about the conceptual picture of the Web graph?

Bow-tie Structure of the Web

41

203 million pages, 1.5 billion links [Broder et al. 2000]

What did We Learn/Not Learn ?

42

Learn:

- Some conceptual organization of the Web (i.e., the bowtie)

Not learn:

- **Treats all pages as equal**
 - Google's homepage == my homepage
- **What are the most important pages**
 - How many pages have k in-links as a function of k ?
The degree distribution: $\sim 1/k^2$
 - Link analysis ranking -- as done by search engines (PageRank)
- **Internal structure inside giant SCC**
 - Clusters, implicit communities?
- **How far apart are nodes in the giant SCC:**
 - Distance = # of edges in shortest path
 - Avg = 16 [Broder et al.]
