Chapter 10: File System

Silberschatz, Galvin and Gagne @2013

File Concept

- Contiguous logical address space
- Types:

 - numeric
 - character
 - binary
 - Program
- Contents defined by file's creator
 - Many types
 - · Consider text file, source file, executable file

File Operations

- File is an abstract data type
- Write at write pointer location
- Read at read pointer location
- Reposition within file seek
- Delete
- **Open(F_i)** search the directory structure on disk for entry F_{ii} and move the content of entry to memory
- Close (F_i) move the content of entry F_i in memory to directory structure on disk

Chapter 10: File System

- File Concept
- Access Methods
- Disk and Directory Structure
- File-System Mounting
- File Sharing
- Protection

File Attributes

- Name only information kept in human-readable form
- Identifier unique tag (number) identifies file within file system
- Type needed for systems that support different types
- Location pointer to file location on device
- Size current file size
- Protection controls who can do reading, writing, executing
- Time, date, and user identification data for protection, security, and usage monitoring
- Information about files are kept in the directory structure, which is maintained on the disk
- Many variations, including extended file attributes such as file checksum
- Information kept in the directory structure

Open Files

- Several pieces of data are needed to manage open files:
 - Open-file table: tracks open files
 - File pointer: pointer to last read/write location, per process that has the file open
 - File-open count: counter of number of times a file is open to allow removal of data from open-file table when last processes
 - Disk location of the file: cache of data access information
 - Access rights: per-process access mode information

- To explain the function of file systems
- To describe the interfaces to file systems
- To discuss file-system design tradeoffs, including access methods, file sharing, file locking, and directory structures
- To explore file-system protection

File info Window on Mac OS X

Open File Locking

- Provided by some operating systems and file systems
 - Similar to reader-writer locks
 - Shared lock similar to reader lock several processes can acquire concurrently
 - Exclusive lock similar to writer lock
- Mediates access to a file
- Mandatory or advisory:
 - Mandatory access is denied depending on locks held and requested
 - · Advisory processes can find status of locks and decide what to

File Types - Name, Extension

file type	usual extension	function
executable	exe, com, bin or none	ready-to-run machine- language program
object	obj, o	compiled, machine language, not linked
source code	c, cc, java, pas, asm, a	source code in various languages
batch	bat, sh	commands to the command interpreter
text	txt, doc	textual data, documents
word processor	wp, tex, rtf, doc	various word-processor formats
library	lib, a, so, dll	libraries of routines for programmers
print or view	ps, pdf, jpg	ASCII or binary file in a format for printing or viewing
archive	arc, zip, tar	related files grouped into one file, sometimes com- pressed, for archiving or storage
multimedia	mpeg, mov, rm, mp3, avi	binary file containing audio or A/V information

Access Methods

■ Sequential Access

read next write next reset

no read after last write

■ Direct Access - file is fixed length logical records

read n write n position to n read next write next rewrite n

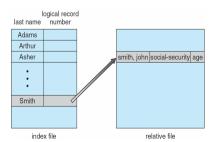

n = relative block number

- Relative block numbers allow OS to decide where file should be placed
 - See allocation problem in Ch 11

Example of Index and Relative Files

File Structure

- None sequence of words, bytes
- Simple record structure
- Lines
- Fixed length
- Variable length
- Complex Structures
 - Formatted document Relocatable load file
- Can simulate last two with first method by inserting appropriate control characters
- Who decides:
 - Operating system
 - Program

Simulation of Sequential Access on

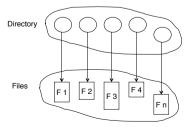

Direct-access File

Directory Structure

A collection of nodes containing information about all files

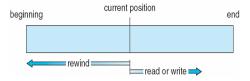

Both the directory structure and the files reside on disk

Sequential-access File

Other Access Methods

- Can be built on top of base methods
- General involve creation of an index for the file
- Keep index in memory for fast determination of location of data to be operated on (consider UPC code plus record of data about that item)
- If too large, index (in memory) of the index (on disk)
- IBM indexed sequential-access method (ISAM)
 - Small master index, points to disk blocks of secondary index
 - · File kept sorted on a defined key
 - All done by the OS
- VMS operating system provides index and relative files as another example

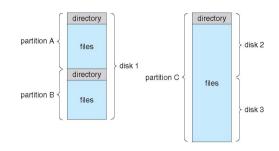

Disk Structure

- Disk can be subdivided into partitions
- Disks or partitions can be RAID protected against failure
- Disk or partition can be used raw without a file system, or formatted with a file system
- Partitions also known as minidisks, slices
- Entity containing file system known as a volume
- Each volume containing file system also tracks that file system's info in device directory or volume table of contents
- As well as general-purpose file systems there are many special -purpose file systems, frequently all within the same operating system or computer

A Typical File-system Organization

■ Efficiency - locating a file quickly

■ Naming – convenient to users

programs, all games, ...)

• Two users can have same name for different files The same file can have several different names

■ Grouping – logical grouping of files by properties, (e.g., all Java

Organize the Directory (Logically) to Obtain

Single-Level Directory

Types of File Systems

■ But systems frequently have many file systems, some general- and

• tmpfs - memory-based volatile FS for fast, temporary I/O

ctfs – contract file system for managing daemons

 procfs – kernel interface to process structures ufs, zfs – general purpose file systems

objfs - interface into kernel memory to get kernel symbols for

lofs – loopback file system allows one FS to be accessed in place

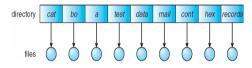

■ We mostly talk of general-purpose file systems

some special- purpose

Consider Solaris has

debugging

■ A single directory for all users

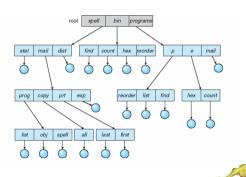

Naming problem

Grouping problem

Tree-Structured Directories

Tree-Structured Directories (Cont.)

- Efficient searching
- Grouping Capability
- Current directory (working directory)
 - od /spell/mail/prog
 - type list

Operations Performed on Directory

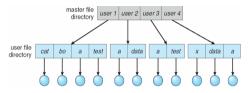

- Search for a file
- Create a file
- Delete a file
- List a directory
- Rename a file
- Traverse the file system

Two-Level Directory

■ Separate directory for each user

- Can have the same file name for different user
- Efficient searching
- No grouping capability

Tree-Structured Directories (Cont)

- Absolute or relative path name
- Creating a new file is done in current directory
- Delete a file

rm <file-name>

■ Creating a new subdirectory is done in current directory

mkdir <dir-name>

Example: if in current directory /mail mkdir count

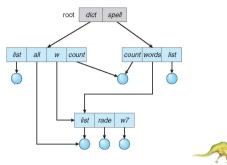

Deleting "mail" ⇒ deleting the entire subtree rooted by "mail

Acyclic-Graph Directories

■ Have shared subdirectories and files

- How do we guarantee no cycles?
 - · Allow only links to file not subdirectories
 - Every time a new link is added use a cycle detection algorithm to determine whether it is OK

General Graph Directory (Cont.)

File Sharing

- Sharing of files on multi-user systems is desirable
- Sharing may be done through a protection scheme
- On distributed systems, files may be shared across a network
- Network File System (NFS) is a common distributed file-sharing method
- If multi-user system
 - User IDs identify users, allowing permissions and protections to be per
 - Group IDs allow users to be in groups, permitting group access rights
 - Owner of a file / directory
 - Group of a file / directory

Acyclic-Graph Directories (Cont.)

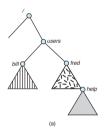

- Two different names (aliasing)
- If dict deletes list ⇒ dangling pointer
 - Backpointers, so we can delete all pointers Variable size records a problem
 - Backpointers using a daisy chain organization
 - Entry-hold-count solution
- New directory entry type
 - Link another name (pointer) to an existing file
 - Resolve the link follow pointer to locate the file

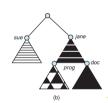

File System Mounting

- A file system must be mounted before it can be accessed
- A unmounted file system (i.e., Fig. 10-11(b)) is mounted at a

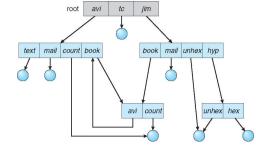

File Sharing - Remote File Systems

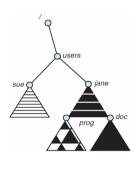

- Uses networking to allow file system access between systems
 - Manually via programs like FTP
 - Automatically, seamlessly using distributed file systems
 - Semi automatically via the world wide web
- Client-server model allows clients to mount remote file systems from
 - Server can serve multiple clients
 - Client and user-on-client identification is insecure or complicated
 - NFS is standard UNIX client-server file sharing protocol
 - CIFS is standard Windows protocol
 - Standard operating system file calls are translated into remote calls
- Distributed Information Systems (distributed naming services) such as LDAP, DNS, NIS, Active Directory implement unified access to information needed for remote computing

Mount Point

Protection

- File owner/creator should be able to control:
 - what can be done
 - by whom
- Types of access
 - Read
 - Write
 - Execute
 - Append
 - Delete
 - List

Access Lists and Groups

- Mode of access: read, write, execute
- Three classes of users on Unix / Linux

a) owner access 7 ⇒ 111 RWX
b) group access 6 ⇒ 110 RWX
c) public access 1 ⇒ 001

- Ask manager to create a group (unique name), say G, and add some users to the group.
- For a particular file (say *game*) or subdirectory, define an appropriate access.

owner group public

Attach a group to a file

chgrp G gam
