# LECTURE 7: NETWORK FORMATION PROCESSES

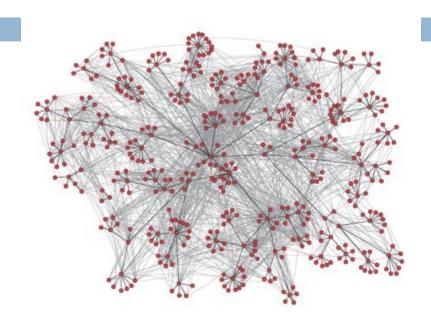

#### **Network Formation Processes**

# What do we observe that needs explaining

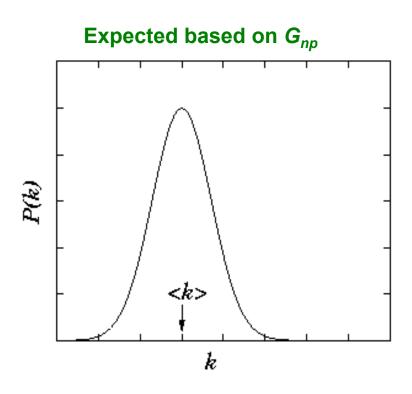

- Small-world model?
  - Diameter
  - Clustering coefficient

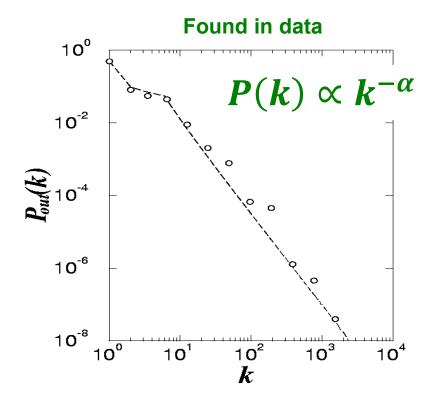

- Node degree distribution
  - What fraction of nodes has degree k (as a function of k)?
  - Prediction from simple random graph models: p(k) =exponential function of k
  - Observation: Power-law:  $p(k) = k^{-\alpha}$

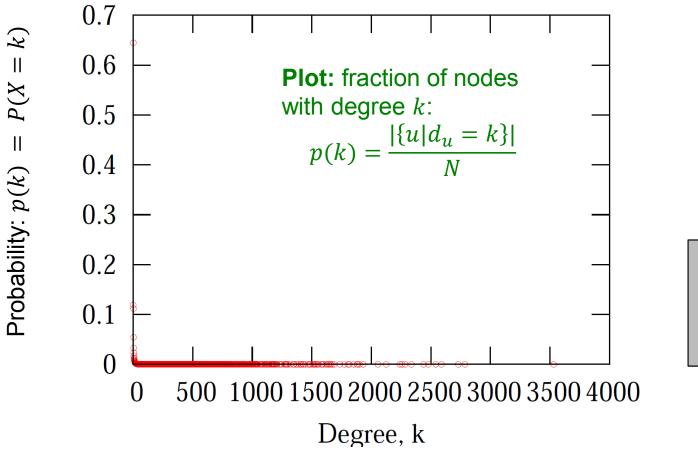

## Degree Distributions

## Node Degrees in Networks

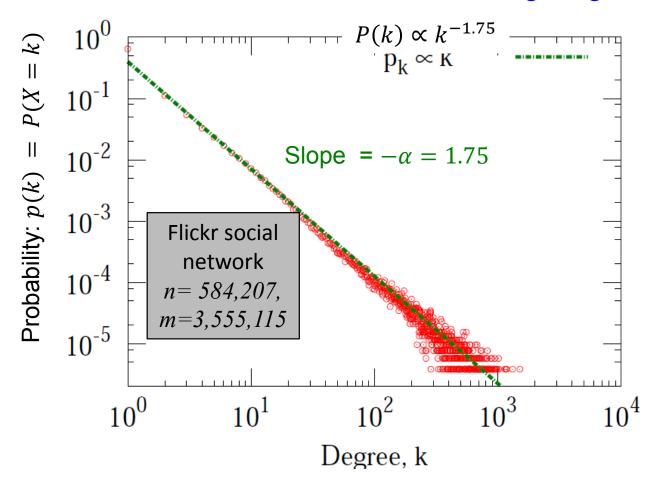

#### lacksquare Take a network, plot a histogram of $oldsymbol{P}(oldsymbol{k})$ vs. $oldsymbol{k}$

Flickr social network n = 584,207,m = 3,555,115

## Node Degrees in Networks

#### □ Plot the same data on log-log scale:

#### How to distinguish:

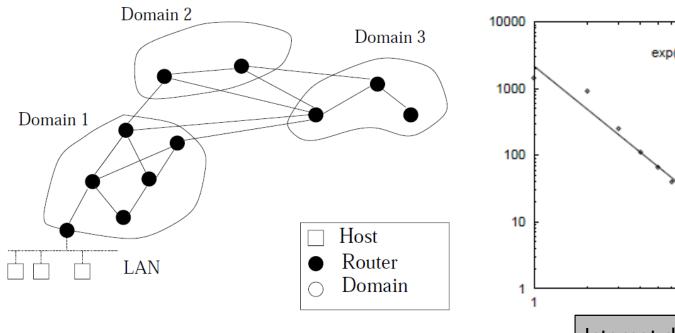

$$P(k) \propto \exp(-k)$$
 vs.  $P(k) \propto k^{-\alpha}$ ?

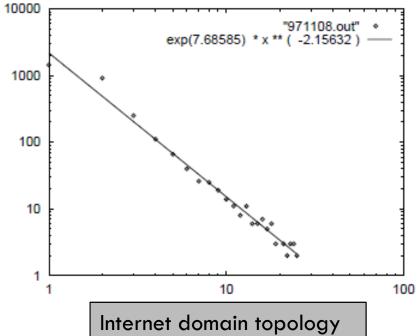

#### Take logarithms:

if 
$$y = f(x) = e^{-x}$$
 then  $\log(y) = -x$   
If  $y = x^{-\alpha}$  then  $\log(y) = -\alpha \log(x)$   
So, on log-log axis power-law looks like a straight line of slope  $-\alpha$ !

## Node Degrees: Faloutsos<sup>3</sup>

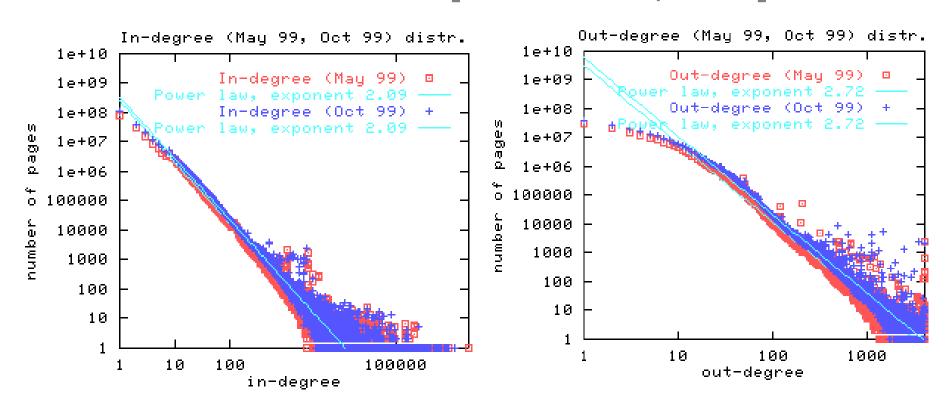

## Internet Autonomous Systems [Faloutsos, Faloutsos and Faloutsos, 1999]

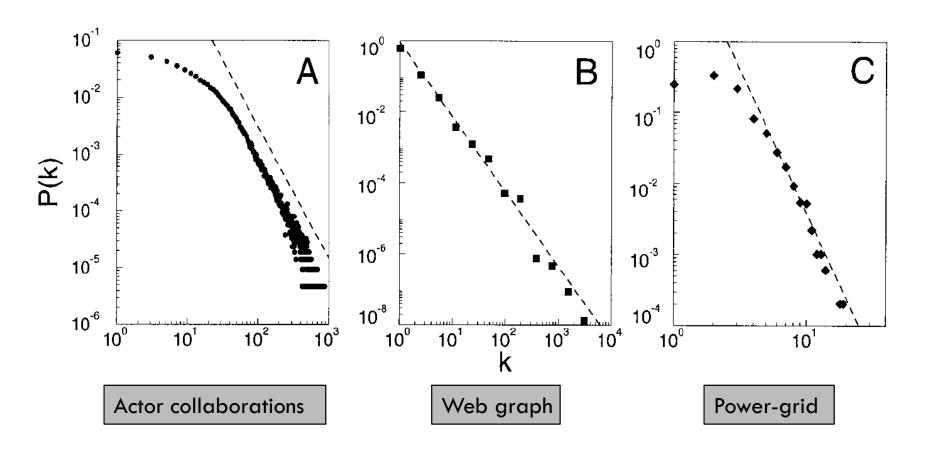

## Node Degrees: Web

#### □ The World Wide Web [Broder et al., 2000]

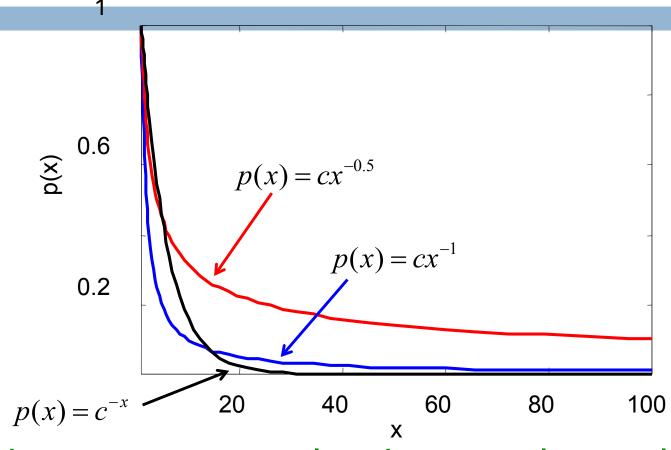

## Node Degrees: Barabasi&Albert

#### Other Networks [Barabasi-Albert, 1999]

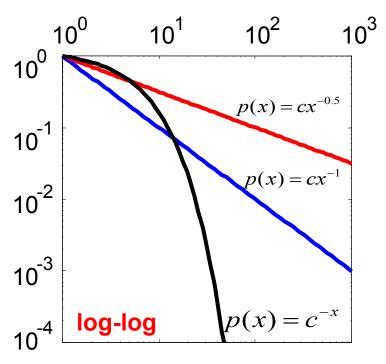

## Exponential vs. Power-Law

 $\square$  Above a certain x value, the power law is always higher than the exponential!

## Exponential vs. Power-Law

#### Power-law vs. Exponential on log-log and log-lin scales

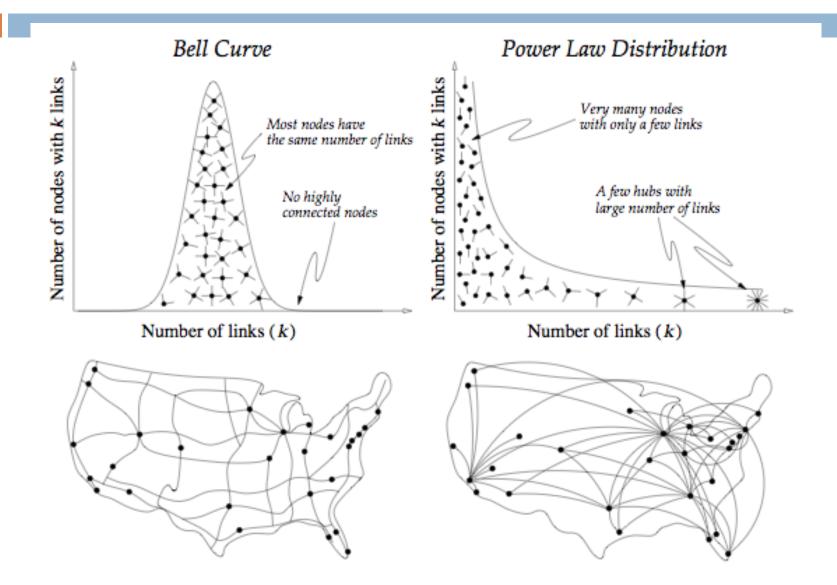

x ... logarithmic axis y ... logarithmic axis

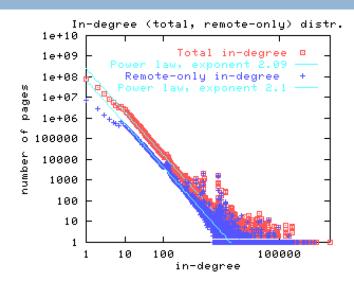

x ... linear y ... logarithmic

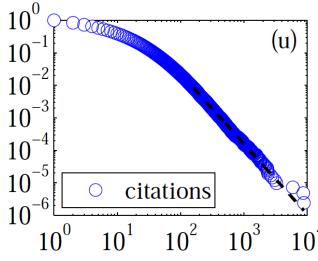

## Exponential vs. Power-Law

## Power-Law Degree Exponents

- Power-law degree exponent is typically 2 < α < 3</li>
  - Web graph:
    - $\alpha_{in} = 2.1$ ,  $\alpha_{out} = 2.4$  [Broder et al. 00]
  - Autonomous systems:
    - $\alpha = 2.4 \, [Faloutsos^3, 99]$
  - Actor-collaborations:
    - $\alpha = 2.3$  [Barabasi-Albert 00]
  - Citations to papers:
    - $\alpha \approx 3$  [Redner 98]
  - Online social networks:
    - $\alpha \approx 2$  [Leskovec et al. 07]

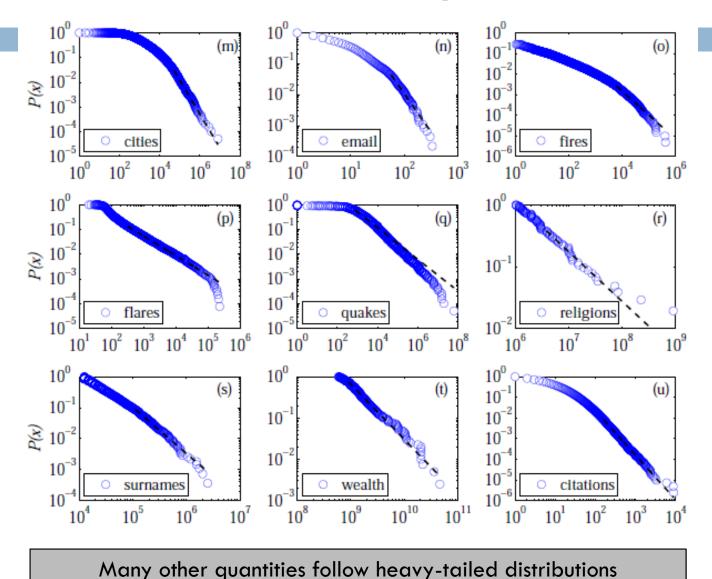

#### Scale-Free Networks

Definition:

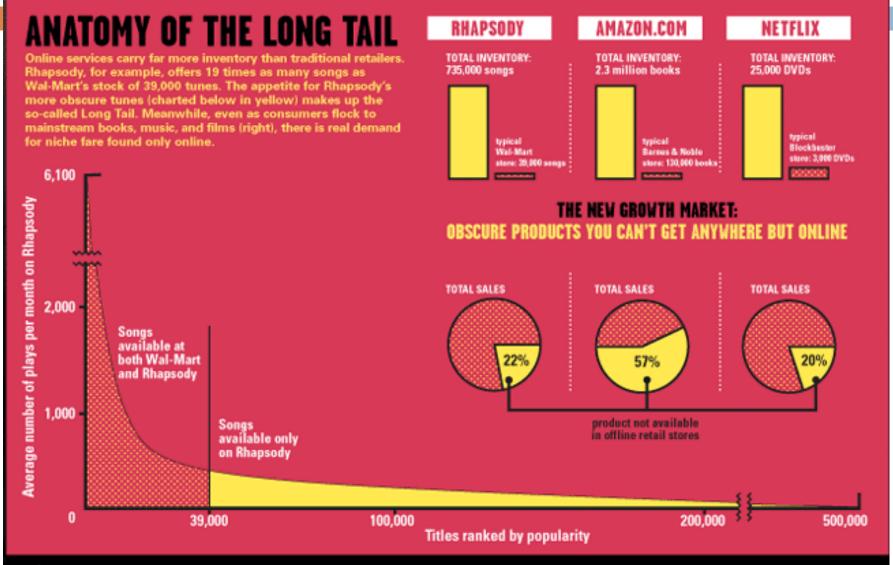

Networks with a power law tail in their degree distribution are called "scale-free networks"

- Where does the name come from?
  - Scale invariance: There is no characteristic scale
  - lacksquare Scale-free function:  $f(ax) = a^{\lambda}f(x)$ 
    - Power-law function:  $f(ax) = a^{\lambda}x^{\lambda} = a^{\lambda}f(x)$

## Power-Laws are Everywhere

## Anatomy of the Long Tail

## Not Everyone Likes Power-Laws ©

## MATHEMATICS OF POWER-LAWS

## Heavy Tailed Distributions

Degrees are heavily skewed:

Distribution P(X > x) is heavy tailed if:

$$\lim_{x\to\infty}\frac{P(X>x)}{e^{-\lambda x}}=\infty$$

□ Note:

■ Normal PDF: 
$$p(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{\frac{(x-\mu)^2}{2\sigma^2}}$$

**Exponential PDF:**  $p(x) = \lambda e^{-\lambda x}$ 

■ then 
$$P(X > x) = 1 - P(X \le x) = e^{-\lambda x}$$

are not heavy tailed!

## Heavy Tailed Distributions

- Various names, kinds and forms:
  - Long tail, Heavy tail, Zipf's law, Pareto's law
- Heavy tailed distributions:
  - □ P(x) is proportional to:

power law  $P(x) \propto x^{-\alpha}$ 

power law with cutoff stretched exponential

log-normal

$$P(x) \propto x^{-\alpha}$$

$$x^{-\alpha} e^{-\lambda x}$$

$$x^{\beta-1} e^{-\lambda x^{\beta}}$$

$$\frac{1}{x} \exp \left[ -\frac{(\ln x - \mu)^2}{2\sigma^2} \right]$$

### Mathematics of Power-laws

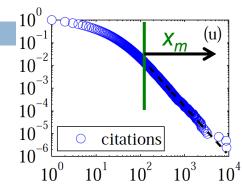

#### What is the normalizing constant?

$$p(x) = Z x^{-\alpha} Z = ?$$

Continuous approximation

$$1 = \int_{x_{min}}^{\infty} p(x) dx = Z \int_{x_m}^{\infty} x^{-\alpha} dx$$

$$\square \Rightarrow Z = (\alpha - 1)x_m^{\alpha - 1}$$

p(x) diverges as  $x \rightarrow 0$ so  $x_m$  is the minimum value of the power-law distribution  $x \in [x_m, \infty]$ 

$$p(x) = \frac{\alpha - 1}{x_m} \left(\frac{x}{x_m}\right)^{-\alpha}$$

#### Mathematics of Power-laws

What's the expectation of a power-law random variable x?

$$\square E[x] = \int_{x_m}^{\infty} x \, p(x) dx = z \int_{x_m}^{\infty} x^{-\alpha+1} dx$$

$$\Box = -\frac{Z}{2-\alpha} [x^{2-\alpha}]_{x_m}^{\infty} = -\frac{(\alpha-1)x_m^{\alpha-1}}{2-\alpha} [\infty^{2-\alpha} - x_m^{2-\alpha}]$$
Need:  $\alpha > 2$ !

$$\Rightarrow E[x] = \frac{\alpha - 1}{\alpha - 2} x_m$$

Power-law density:

$$p(x) = \frac{\alpha - 1}{x_m} \left(\frac{x}{x_m}\right)^{-\alpha}$$
$$Z = \frac{\alpha - 1}{x_m^{1 - \alpha}}$$

#### Mathematics of Power-Laws

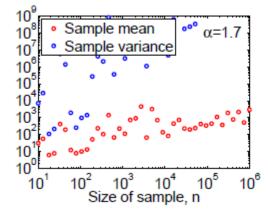

#### Power-laws have infinite moments!

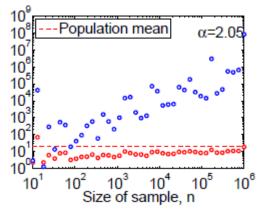

$$E[x] = \frac{\alpha - 1}{\alpha - 2} x_m$$

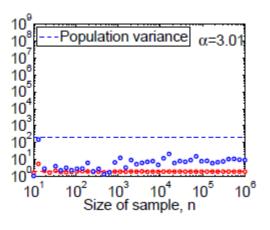

$$\blacksquare \text{ If } \alpha \leq 2 : E[x] = \infty$$

In real networks  $2 < \alpha < 3$  so: E[x] = const $Var[x] = \infty$ 

- Average is meaningless, as the variance is too high!
- □ Sample average of n samples from a power-law with exponent  $\alpha$ :

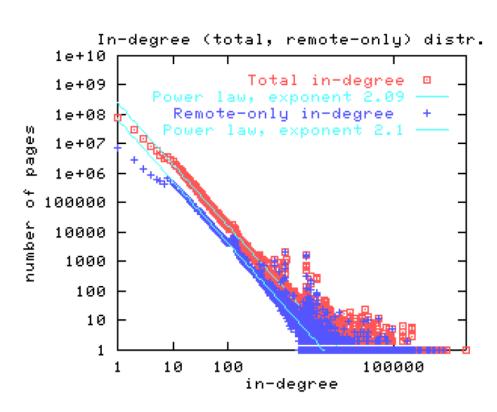

## Estimating Power-Law Exponent $\alpha$

#### Estimating $\alpha$ from data:

- (1) Fit a line on log-log axis using least squares:
  - Solve  $\underset{\alpha}{arg} \min_{\alpha} (\log(y) \alpha \log(x))^2$

BAD!

## Estimating Power-Law Exponent $\alpha$

#### Estimating $\alpha$ from data:

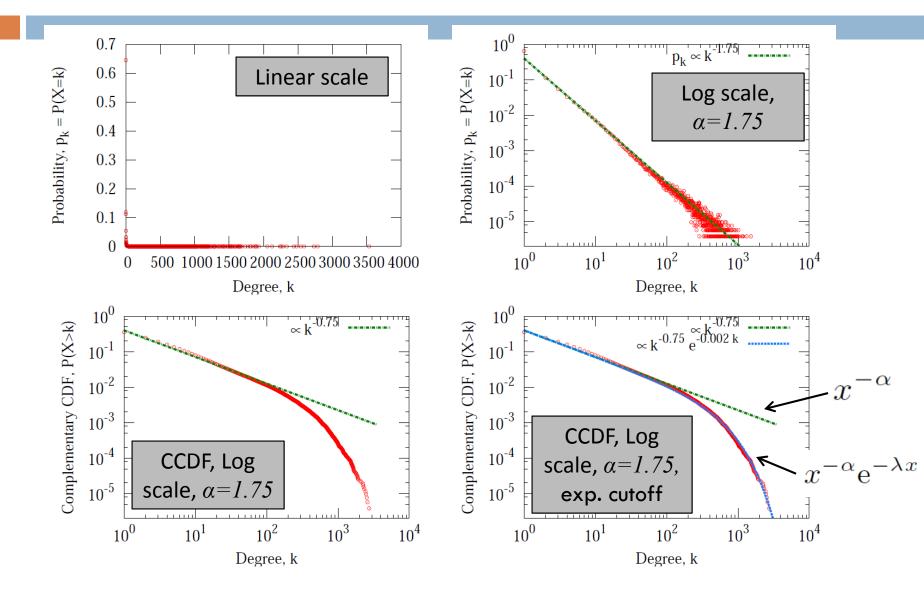

OK!

□ Plot Complementary CDF (CCDF)  $P(X \ge x)$ . Then the estimated  $\alpha = 1 + \alpha'$ where  $\alpha'$  is the slope of P(X > x).

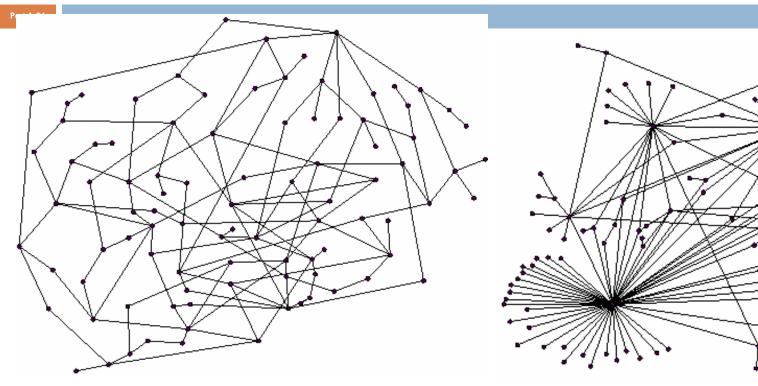

□ If  $p(x) = P(X = x) \propto x^{-\alpha}$ then  $P(X \ge x) \propto x^{-(\alpha-1)}$ 

$$P(X \ge x) = \sum_{j=x}^{\infty} p(j) \approx \int_{x}^{\infty} Z j^{-\alpha} dj =$$

## Flickr: Fitting Degree Exponent

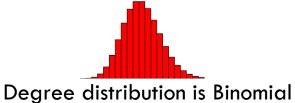

### Random vs. Scale-free network

#### Random network

(Erdos-Renyi random graph)

#### Scale-free (power-law) network

Degree distribution is Power-law

# MODEL: PREFERENTIAL ATTACHMENT

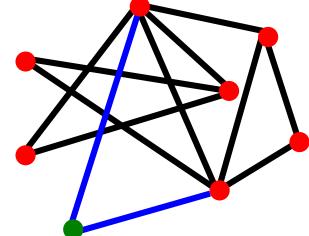

#### Model: Preferential attachment

#### Preferential attachment

[Price '65, Albert-Barabasi '99, Mitzenmacher '03]

- Nodes arrive in order 1,2,...,n
- $\blacksquare$  At step j, let  $d_i$  be the degree of node  $i \le j$
- $\blacksquare$  A new node j arrives and creates m out-links
- Prob. of j linking to a previous node i is proportional to degree  $d_i$  of node i

$$P(j \to i) = \frac{d_i}{\sum_k d_k}$$

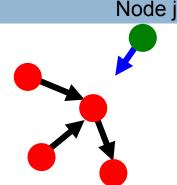

#### Rich Get Richer

- New nodes are more likely to link to nodes that already have high degree
- ☐ Herbert Simon's result:
  - Power-laws arise from "Rich get richer" (cumulative advantage)
- □ Examples [Price 65]:
  - Citations: New citations to a paper are proportional to the number it already has

#### The Exact Model

#### We will analyze the following model:

- $\square$  Nodes arrive in order 1,2,3, ..., n
- □ When node j is created it makes a single out-link to an earlier node i chosen:
  - lacktriangleright 1) With prob. p, j links to i chosen uniformly at random (from among all earlier nodes)
  - **2)** With prob. 1 p, node j chooses node i uniformly at random and links to a node i points to.
    - This is same as saying: With prob. 1-p, node j links to node u with prob. proportional to  $d_u$  (the in-degree of u)
    - Our graph is directed: Every node has out-degree 1.

#### The Model Givens Power-Laws

Claim: The described model generates networks where the fraction of nodes with in-degree k scales as:

$$P(d_i = k) \propto k^{-(1 + \frac{1}{q})}$$

where q=1-p

So we get power-law degree distribution with exponent:

$$\alpha = 1 + \frac{1}{1 - p}$$

#### Preferential attachment: Good news

- □ Preferential attachment gives power-law degrees
- Intuitively reasonable process
- $\square$  Can tune p to get the observed exponent
  - $\blacksquare$  On the web,  $P[node\ has\ degree\ d] \sim d^{-2.1}$

## There are also other network formation mechanisms that generate scale-free networks:

- Random surfer model [Blum-Mugizi]
- Copying model [Kleinberg et al.]
- Forest Fire model [Leskovec et al.]
