Chapter 6: Process Synchronization

Operating System Concepts - 9th Edition

Objectives

- To present both software and hardware solutions of the critical-section problem
- To examine several classical process-synchronization problems
- To explore several tools that are used to solve process synchronization problems

Background

- Processes can execute concurrently
- May be interrupted at any time, partially completing execution
- Concurrent access to shared data may result in data inconsistency
- Maintaining data consistency requires mechanisms to ensure the orderly execution of cooperating
- Illustration of the problem: Suppose that we warried to provide a solution to the consumer-producer problem that fills all the buffers. We can do so by having an integer counter that keeps track of the number of full buffers. Initially, counter: is set to 0.1 is incremented by the producer after it produces a new buffer and is decremented by the consumer after it consumes a buffer.

Producer

```
while (true) {
    /* produce an item in next produced */
    while (counter == BUFFER SIZE) ;
         /* do nothing */
    buffer[in] = next produced;
    in = (in + 1) % BUFFER SIZE;
```

Consumer

```
while (true) {
   while (counter == 0)
       ; /* do nothing */
   next consumed = buffer[out];
   out = (out + 1) % BUFFER SIZE;
   counter--;
    /\star consume the item in next consumed \star/
```

Race Condition

counter++ could be implemented as

register1 = counter
register1 = register1 + 1
counter = register1

■ counter-- could be implemented as

register2 = counter register2 = register2 - 1 counter = register2

■ Consider this execution interleaving with "count = 5" initially:

S0: producer execute register! = counter
S1: producer execute register! = register! + 1
S2: consumer execute register2 = counter
S3: consumer execute register2 = register2 - 1
S4: producer execute counter = register1
S5: consumer execute counter = register2

Critical Section Problem

- Consider system of n processes {p_n, p₁, ... p_{n-1}}
- Each process has critical section segment of code
 - Process may be changing common variables, updating table, writing file, etc. . When one process in critical section, no other may be in its critical section
- Critical section problem is to design protocol to solve this
- Each process must ask permission to enter critical section in entry section, may follow critical section with exit

Critical Section

■ General structure of process p_i is

do { entry section critical section exit section } while (true);

Solution to Critical-Section Problem

- 1. Mutual Exclusion If process P_i is executing in its critical section, then no other processes can be
- Progress If no process is executing in its critical section and there exist some processes that wish to enter their critical section, then the selection of the processes that will enter the critical section next cannot be postponed indefinitely
- Bounded Waiting A bound must exist on the number of times that other processes are allowed to enter their critical sections after a process has made a request to enter its critical section and before that request its grained
 - Assume that each process executes at a nonzero speed
 - No assumption concerning relative speed of the n processes
- Two approaches depending on if kernel is preemptive or non-preemptive
 - Preemptive allows preemption of process when running in kernel mode
 - Non-preemptive runs until exits kernel mode, blocks, or voluntarily yields CPU
 - ▶ Essentially free of race conditions in kernel mode

Peterson's Solution

- Good algorithmic description of solving the problem
- Assume that the load and store instructions are atomic; that is, cannot be interrupted
- The two processes share two variables:
- int turn;
- Boolean flag[2]
- The variable turn indicates whose turn it is to enter the critical section
- The flag array is used to indicate if a process is ready to enter the critical section. flag[i] = true implies that process P_i is ready!

Definition

flag[i] = true turn = i:

} while (true);

 Provable that 1. Mutual exclusion is preserved

while (flag[j] && turn == j);

critical section flag[i] = false;

remainder section

2. Progress requirement is satisfied

3. Bounded-waiting requirement is met

Synchronization Hardware

- Many systems provide hardware support for critical section code
- All solutions below based on idea of locking
- Protecting critical regions via locks
- - Currently running code would execute without preemption Generally too inefficient on multiprocessor systems
 - Operating systems using this not broadly scalable
- Modern machines provide special atomic hardware instructions
 - Atomic = non-interruptible
 - Either test memory word and set value Or swap contents of two memory words

Solution to Critical-section Problem Using Locks

```
critical section
  release lock
       remainder section
} while (TRUE);
```

Solution using test_and_set()

- Shared boolean variable lock, initialized to FALSE
- Solution:

```
while (test and set(&lock))
     : /* do nothing */
  /* critical section */
  lock = false;
  /* remainder section */
} while (true);
```

Bounded-waiting Mutual Exclusion with test_and_set

```
waiting[i] = true;
   key = true;
while (waiting[i] && key)
     key = test and set(&lock);
   waiting[i] = false;
   /* critical section */
  j = (i + 1) % n;
   while ((j != i) && !waiting[j])
    i = (i + 1) % n;
  if (i == i)
     lock = false
      waiting[j] = false;
   /* remainder section */
} while (true);
```

Mutex Locks

test_and_set Instruction

boolean test_and_set (boolean *target)

*target = TRUE;

Algorithm for Process P

- Previous solutions are complicated and generally inaccessible to application programmers
- OS designers build software tools to solve critical section problem
- Simplest is mutex lock
- Product critical regions with it by first acquire() a lock then release() it Boolean variable indicating if lock is available or not
- Calls to acquire() and release() must be atomic
- Usually implemented via hardware atomic instructions
- But this solution requires busy waiting
- This lock therefore called a spinlock

acquire() and release()

```
acquire() {
   while (!available)
     ; /* busy wait */
   available = false;;
release() {
  available = true;
  acquire lock
      critical section
  release lock
      remainder section
} while (true);
```

Semaphore

- Synchronization tool that does not require busy waiting
- Semaphore S integer variable
- Two standard operations modify S: wait() and signal()
- Originally called P() and V()
- Less complicated
- Can only be accessed via two indivisible (atomic) operations

```
wait (S) {
   while (S <= 0)
     ; // busy wait
signal (S) {
```

Semaphore Usage

- Counting semaphore integer value can range over an unrestricted domain
- Binary semaphore integer value can range only between 0 and 1
 - Then a mutex lock
- Can implement a counting semaphore S as a binary semaphore
- Can solve various synchronization problems
- Consider P₁ and P₂ that require S₁ to happen before S₂

```
signal(synch);
P2:
  wait(synch)
```

Semaphore Implementation

- Must guarantee that no two processes can execute wait () and signal () on the same semaphore at the same time
- Thus, implementation becomes the critical section problem where the wait and signal code are placed in the critical section
 - Could now have busy waiting in critical section implementation.
 - > But implementation code is short
 - Little busy waiting if critical section rarely occupied
- Note that applications may spend lots of time in critical sections and therefore this is not a good solution

Semaphore Implementation with no Busy waiting

- With each semaphore there is an associated waiting queue
- Each entry in a waiting queue has two data items
 - value (of type integer)

Two operations:

- pointer to next record in the list
- block place the process invoking the operation on the appropriate waiting queue
- wakeup remove one of processes in the waiting queue and place it in the ready queue

Semaphore Implementation with no Busy waiting (Cont.)

```
typedef struct{
   int value;
} semaphore;
wait(semaphore *S) {
   S->value--;
   if (S->value < 0) {
   add this process to S->list;
       block();
signal(semaphore *S) {
   S->value++;
   if (S->value <= 0) {
   remove a process P from S->list;
       wakeup(P);
```

Deadlock and Starvation

- Deadlock two or more processes are waiting indefinitely for an event that can be caused by only one of the waiting processes
- Let S and Q be two semaphores initialized to 1

```
wait(S);
                          wait(Q);
wait(0);
                         wait(S);
signal(S);
                         signal(Q);
signal(Q);
                         signal(S);
```

- A process may never be removed from the semaphore queue in which it is suspended Priority Inversion – Scheduling problem when lower-priority process holds a lock needed by higher-priority process
 - Solved via priority-inheritance protocol

Classical Problems of Synchronization

- Classical problems used to test newly-proposed synchronization schemes
 - Bounded-Buffer Problem
 - Readers and Writers Problem
 - Dining-Philosophers Problem

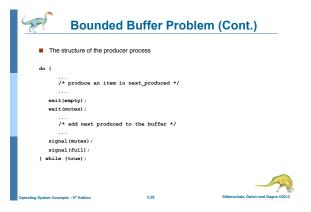

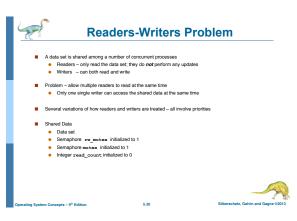

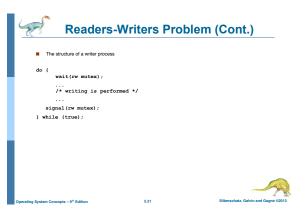

Bounded-Buffer Problem

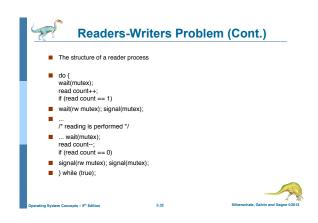

- Semaphore mutex initialized to the value 1
- Semaphore **full** initialized to the value 0
- Semaphore empty initialized to the value n

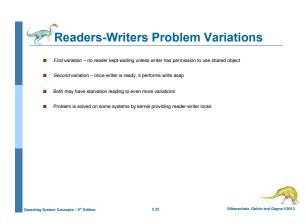

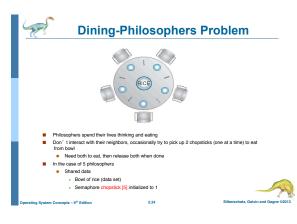

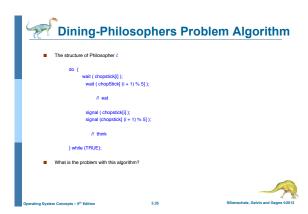

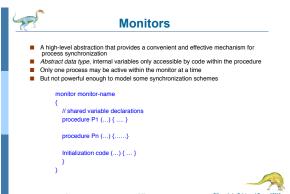

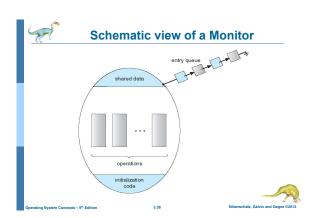

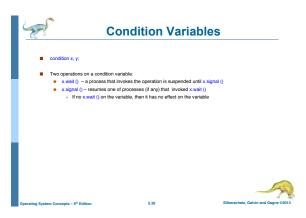

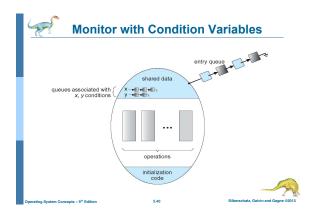

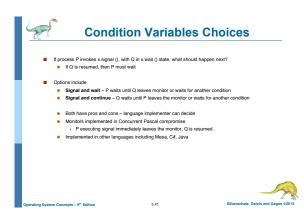

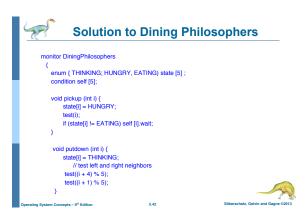

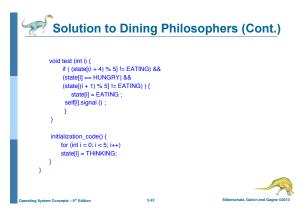

```
Solution to Dining Philosophers (Cont.)

1 Each philosopher / invokes the operations pickup() and putdown() in the following sequence:

Dining/Philosophers pickup (i);

EAT

Dining/Philosophers.putdown (i);

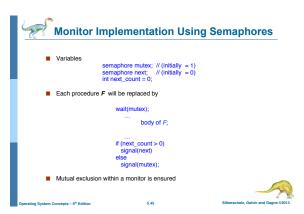

1 No deadlock, but starvation is possible

Dining/Philosophers.putdown (i);

Solution to Dining/Philosophers.putdown (ii);

Solution to Dining Philosophers pickup (ii);

Solution to Dining Philosophers (Cont.)
```

For each condition variable x, we have:

semaphore x_sem; // (initially = 0) int x count = 0;

■ The operation x.wait can be implemented as:

x-count++: if (next_count > 0) signal(next); signal(mutex); wait(x_sem); x-count--;

Monitor Implementation (Cont.)

```
if (x-count > 0) {
   next_count++;
    signal(x_sem);
    wait(next);
   next_count--
```

Synchronization Examples

- Windows XP
- Linux

Solaris Synchronization

- Implements a variety of locks to support multitasking, multithreading (including real-time threads), and multiprocessing
- Uses adaptive mutexes for efficiency when protecting data from short code segments
 - Starts as a standard semaphore spin-lock
 - If lock held, and by a thread running on another CPU, spins
 - If lock held by non-run-state thread, block and sleep waiting for signal of lock being released
- Uses condition variables
- Uses readers-writers locks when longer sections of code need access to data
- Uses turnstiles to order the list of threads waiting to acquire either an adaptive mutex or reader-writer lock Turnstiles are per-lock-holding-thread, not per-object

Windows XP Synchronization

- Uses interrupt masks to protect access to global resources on uniprocessor systems
- Uses spinlocks on multiprocessor systems
- Spinlocking-thread will never be preempted
- Also provides dispatcher objects user-land which may act mutexes, semaphores, events, and timers

 - . An event acts much like a condition variable
 - Timers notify one or more thread when time expired
 - Dispatcher objects either signaled-state (object available) or non-signaled state (thread will block)

Linux Synchronization

- Version 2.6 and later, fully preemptive
- Linux provides:
 - semaphores

- On single-cpu system, spinlocks replaced by enabling and disabling kernel preemption

Pthreads Synchronization

- Pthreads API is OS-independent
- - mutex locks condition variables
- Non-portable extensions include:
 - read-write locks
 - spinlocks
